Smart Wearable for Workplace Safety

An IoT-powered wearable device for monitoring worker and workplace safety in industrial environments

MOTIVATION

WHY IT'S IMPORTANT...

- Workplace safety is of critical importance
- Especially in places like Sri Lanka, where safety regulations and best-practices often go unheeded
- In Sri Lanka, nearly 4,000 workplace accidents are reported daily and nearly 600,000 productive, working-days are lost
- The main clause under the Occupational Safety & Health act of Sri Lanka covers only around 30% of the workforce.

It's clear that occupational safety and health is very often an under-rated concern of factory owners and employers across the Island

So, what's *our* solution...?

Reference: <https://www.ilo.org/colombo/areasofwork/safety-and-health-at-work/lang-en/index.htm>

A smart wearable for monitoring worker and workplace safety

- It should integrate seamlessly into the wearer's daily-routine.
- It should be non-invasive
- It should send data wirelessly to a central data-collector (in this case, a MySQL database)
- It should facilitate real-time monitoring and be capable of warning the wearer in case of danger
- Should be durable and long-lasting even in industrial environments

Implementation Details

A BRIEF DESCRIPTION OF SOME IMPLEMENTATION DETAILS

- For the prototype we use a NodeMCU board and connect several sensors for taking readings
- Each of the sensors' readings are sent to a MySQL database over a wireless network using the MQTT protocol. Our MQTT broker of choice was the Mosquitto broker
- The readings are sent to Node-Red, in which we define our workflows for the data
- From Node-Red, we insert the data into a MySQL database where it can be fetched by our website and used for further analysis
- Our intention is to make the wearable a modular device which allows for customization of the sensors as required by various unique industrial environments

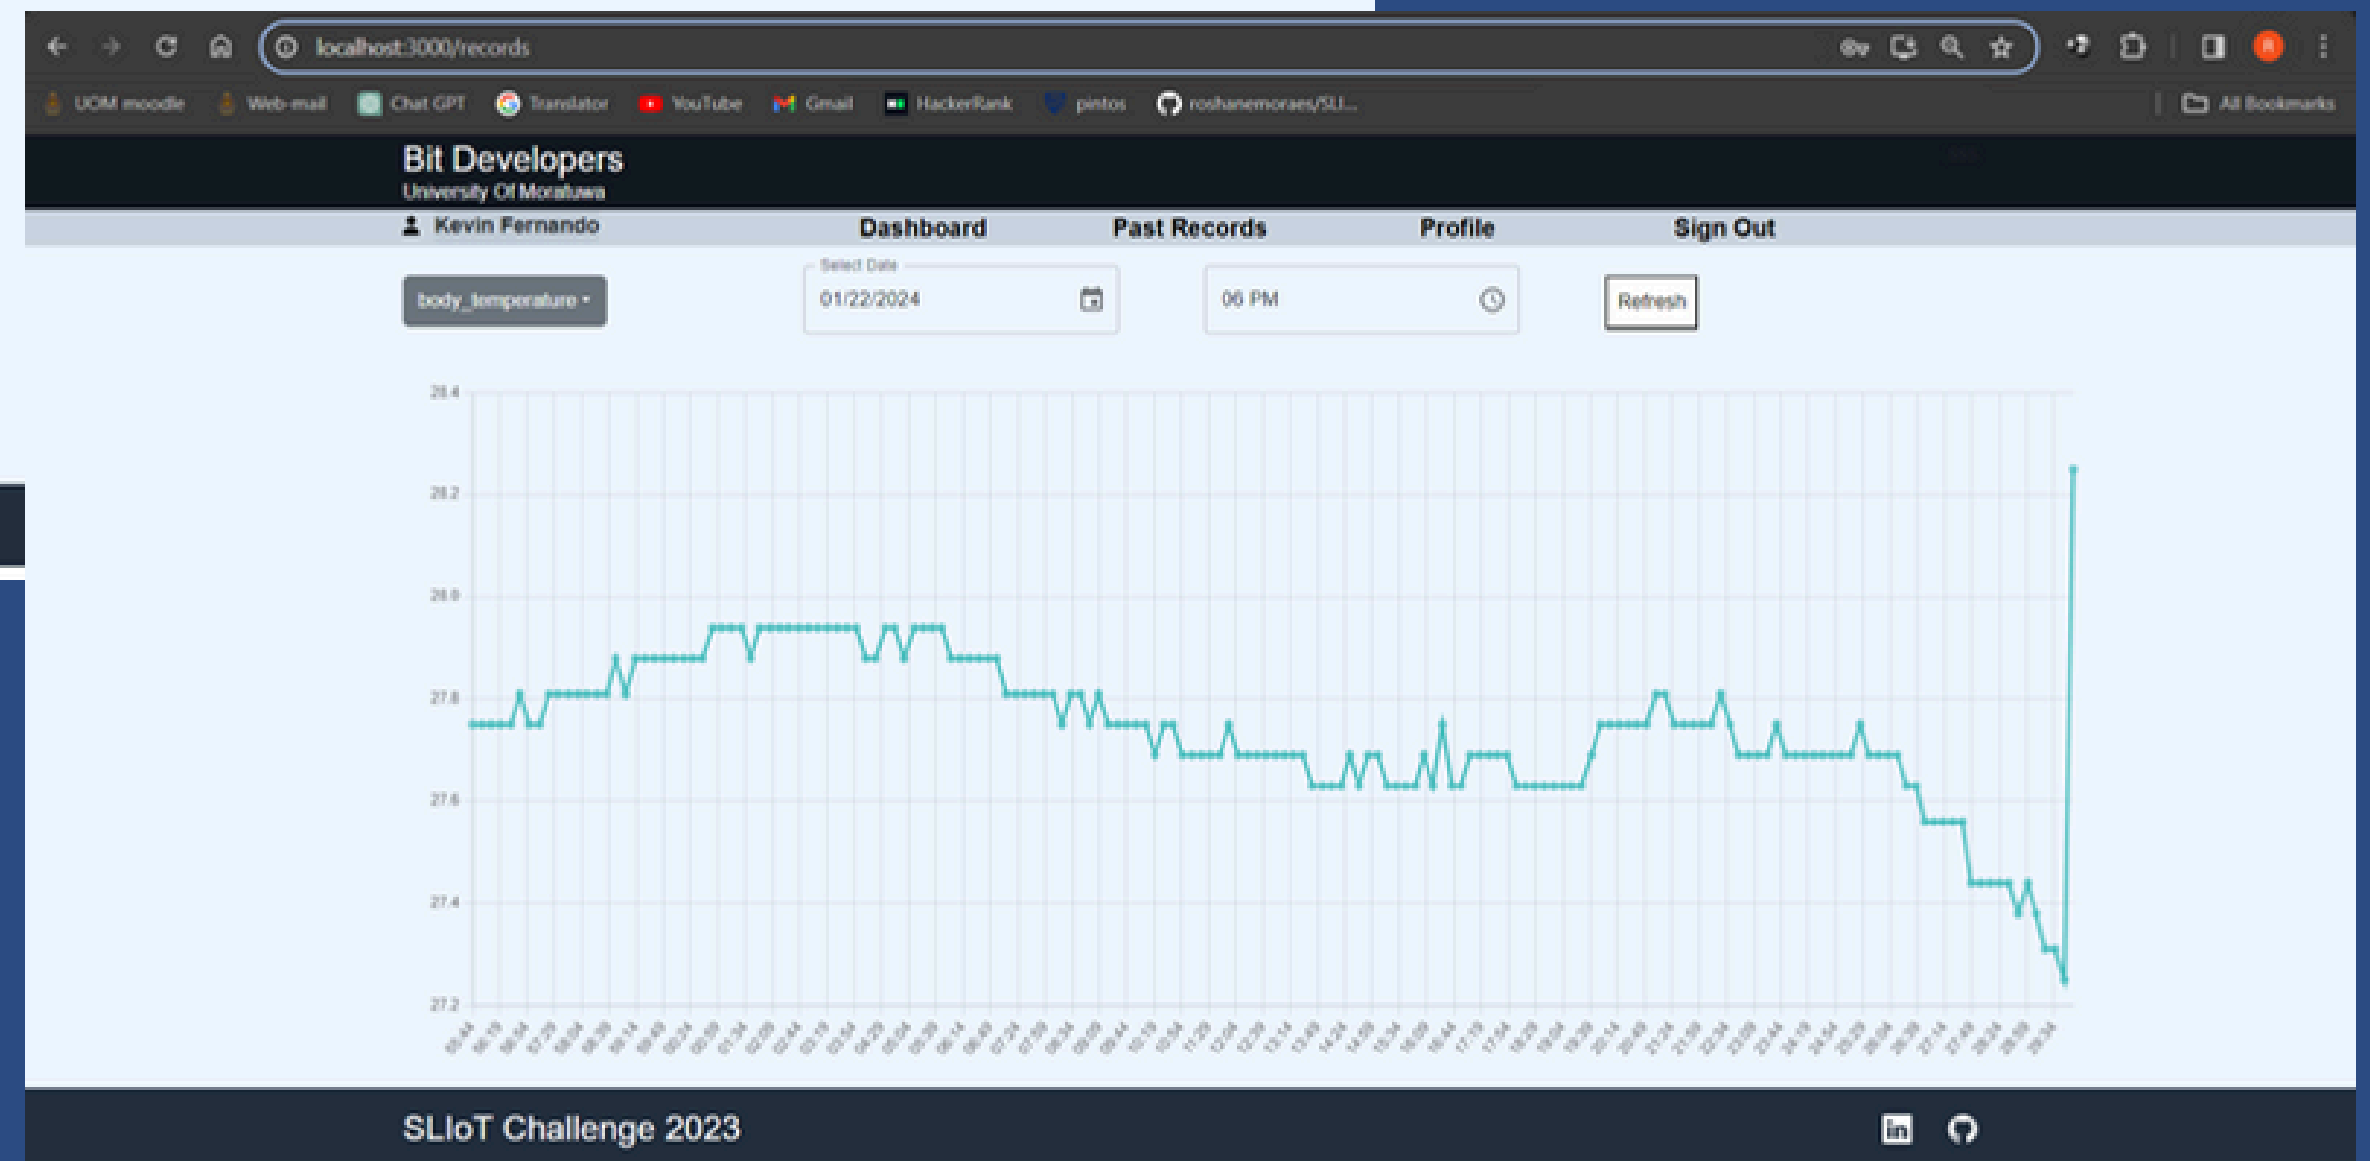

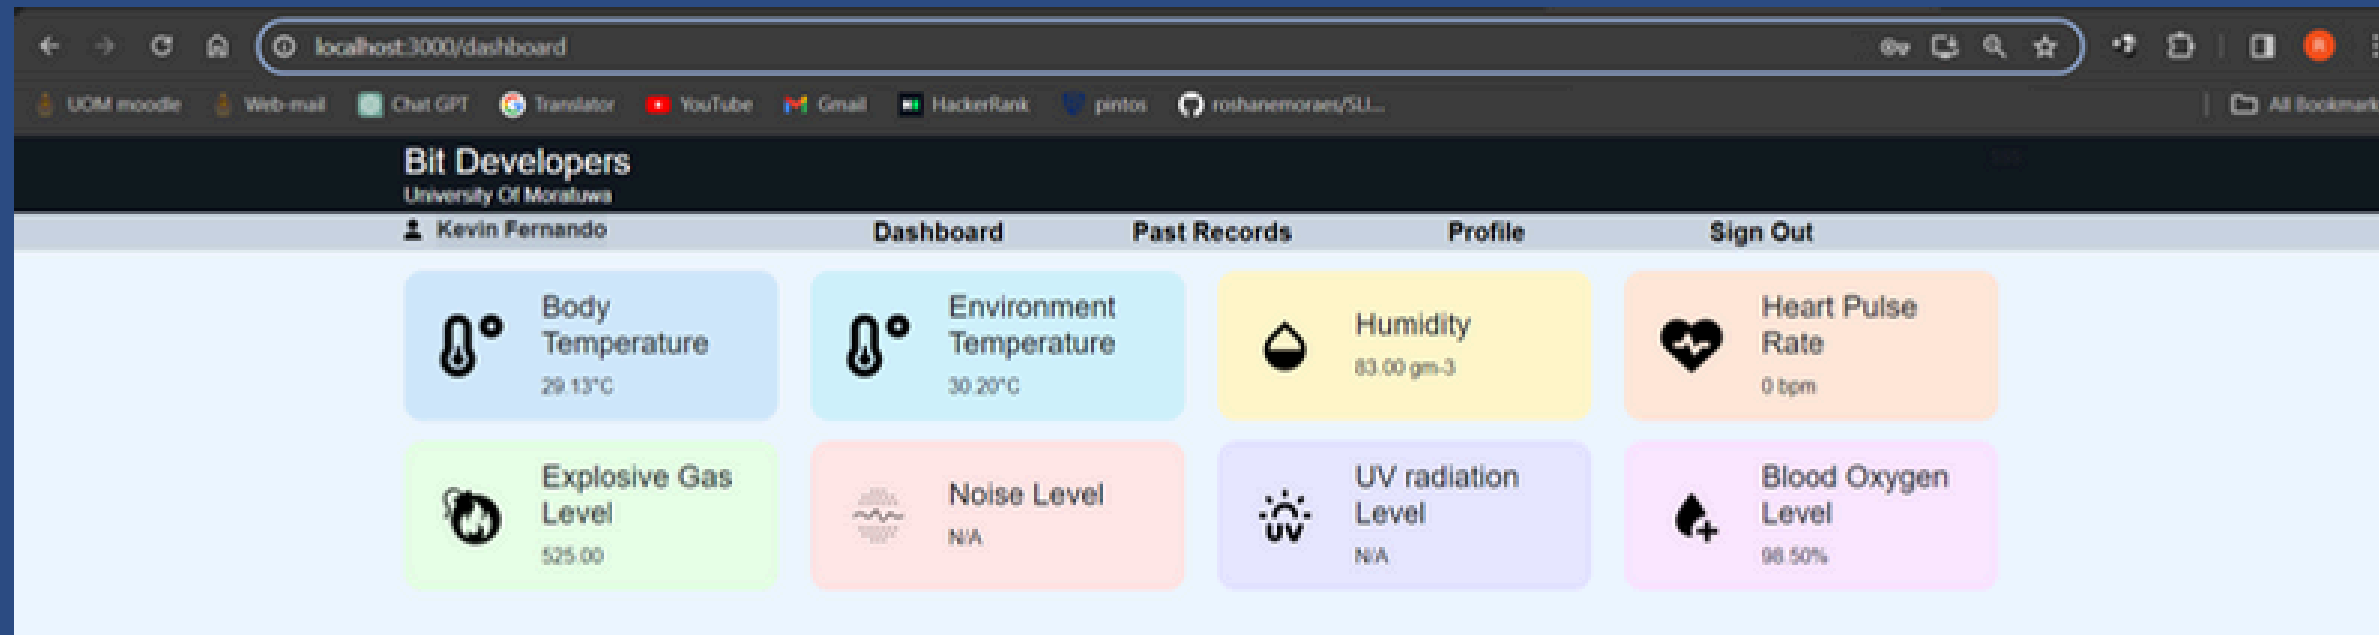

The Stationary Module

- In addition to the wearable device we can optionally build a stationary device which can include common sensors
- This will allow for more customization and flexibility while also reducing the cost
- If an anomaly or hazardous condition is detected, the workers in the specific area can be alerted by checking their GPS coordinates
